## **Alternate Tide Prediction Form**

The tide prediction form provided in the Advanced Piloting manual is based on having a regular tidal pattern where each cycle, from low to high and back to low, takes about 12 hours. Each half cycle, low to high or high to low, occurs in approximately 6 hours. If the cycle duration is irregular or the half cycle duration is significantly different from 6 hours, the results may not be satisfactory. For those circumstances an alternate Tide Prediction Form is available below.

The alternate Tide Prediction Form uses the same procedure as the standard form (Figure 7-4 in the AP manual) for the top half of the form. For the lower half of the alternate Form instead of calculating the "time difference to desired time" calculate the total duration of the half cycle of interest (time of next high or low minus the time of prior low or high). Divide that duration by 6 and record that value in the provided box. In the series of boxes just below, record the time of the prior high or low, and in each of the next 6 boxes, add increments of 1/6th duration. Then compare the desired time to the seven values (time of prior high or low plus 6 others), and select the percentage value representing the time closest to the desired time. The rest of the form is similar to Figure 7-4.

If Table 2 has an  $\begin{bmatrix} * \\ - \end{bmatrix}$  before the height difference multiply the Table 1 height by this factor to get subordinate height Table 2 has a  $\begin{bmatrix} + & or \\ - & \end{bmatrix}$  before the height difference add or subtract that difference to get subordinate height.
